

EOGT gene

EGF domain specific O-linked N-acetylglucosamine transferase

Normal Function

The *EOGT* gene provides instructions for making a protein that modifies certain other proteins by transferring a molecule called N-acetylglucosamine to them. This change, called an O-GlcNAc modification, can affect protein stability and regulate several cellular processes, such as signaling in cells and the first step in the production of proteins from genes (transcription). Little is known about the proteins altered by the *EOGT* protein or what effect the O-GlcNAc modification has on them. Studies suggest that Notch proteins may be modified by *EOGT*. Notch proteins stimulate signaling pathways important during the development of several tissues throughout the body, including the bones, heart, liver, muscles, and blood cells, among others.

Health Conditions Related to Genetic Changes

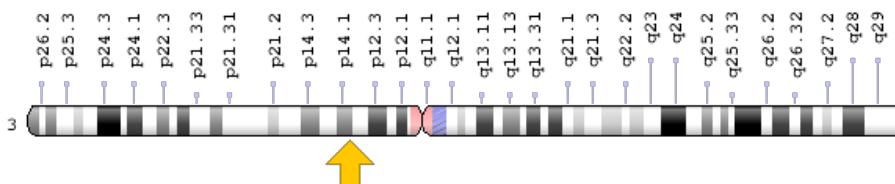

Adams-Oliver syndrome

At least three mutations in the *EOGT* gene have been found in individuals with Adams-Oliver syndrome. This condition is characterized by areas of missing skin (aplasia cutis congenita), usually on the scalp, and malformations of the hands and feet. The most common *EOGT* gene mutation involved in this condition, which is found in the Arab population, leads to an abnormally short protein. The other mutations change single protein building blocks (amino acids) in the *EOGT* protein. Research suggests that the *EOGT* gene mutations reduce or eliminate the protein's ability to transfer N-acetylglucosamine. It is unknown what effect this impairment has on cells or how it leads to the features of Adams-Oliver syndrome.

Chromosomal Location

Cytogenetic Location: 3p14.1, which is the short (p) arm of chromosome 3 at position 14.1

Molecular Location: base pairs 68,975,212 to 69,013,961 on chromosome 3 (Homo sapiens Annotation Release 108, GRCh38.p7) (NCBI)
